

## Number of Distant Cousins

R.E. Butler  
26 June, 2011

I have been surprised by the number of contacts with distant cousins through Ancestry. I think part of the reason is that there are many more distant cousins than close cousins. So I thought I would calculate the number of cousins of each degree, based on an average number of descendants per family.

Let  $c$  = cousin degree. In this case limited to integers.  $c=0$  means siblings,  $c=1$  means first cousins etc.

$n$  = number of generations back from me.  $n=1$  are my parents,  $n=2$  are my grandparents.

The cousin degree is determined by the number of generations back to common ancestors.

$c = n-1$

Let  $d$  = number of descendants per family who have families and produce more descendants.

Siblings,  $c=0$ .  $n = 1$ , Common parents, 1 family.

If there are  $d$  descendants per family, then the number of siblings is  $d-1$

First cousins,  $c = 1$ ,  $n = 2$  Common grandparents. 2 families of grandparents.

My father had  $d-1$  siblings. Each of them had  $d$  children. Total number of first cousins from my father's family is  $d * (d-1)$

My mother had  $d-1$  siblings. Each of them had  $d$  children. Total number of first cousins from my mother's family is  $d * (d-1)$

Total number of first cousins is  $2d * (d-1)$

Second cousins,  $c = 2$ ,  $n = 3$  Common great grandparents, 4 families of great grandparents..

Each grandparent had  $d-1$  siblings. Each of them had  $d$  children of my parents generation, and each of them had  $d$  children of my generation.

Total number of second cousins related to any one of my grandparents =  $(d-1) * d * d$

There are 4 of these families, so the number of second cousins is  $4 * d^2 * (d-1)$

General variable  $c$ .  $n = c+1$  Common ancestors of generation  $n$ .  $2^c$  families with children of the same generation as the common ancestors.

Each of those families produced  $(d-1) * d^c$  children of my generation who are my cousins of degree  $c$ .

The total number of cousins of degree  $c = (2d)^c * (d-1)$

This is intuitively reasonable. If everybody has only 1 child,  $d = 1$ , and nobody has any cousins of any degree.

If the average is 2 children, then the total number of cousins of degree  $c$  is  $4^c$ . Thus with each increase in degree, the number of cousins of that degree is 4 times as many as the previous degree.

The number of ancestors goes up by a factor of 2 for each generation further back, and the number of descendants from each goes up by a factor of  $d$ .

So if  $d =$  an average of 3 children per generation, the number of cousins of each degree is 6 times as many as the previous degree.

What is a reasonable  $d$ ? Well, it currently is low, but it used to be quite a bit larger. If  $d=2$ , every 2 people produce 2 people and the population stays the same over time. Since populations actually increase, maybe a long term average might be 3. Some of my ancestors had 4 or more children who produced more children, so the average could be a lot higher.

But even with small  $d$ , the numbers increase very quickly, as shown in the following table.

If  $d = 2$ , we have 262 thousand 9<sup>th</sup> cousins.

If  $d = 3$ , we have 20 million 9<sup>th</sup> cousins....

This is another way of saying we are all related. All of us with British descent, anyway.

This is reminiscent of the problem of counting the grains of rice on a checker board. If you put 1 on the first square, 2 on the second, times 2 on each subsequent square, then ultimately the count is greater than the grain supply.

But in the case of cousins, you put  $d-1$  siblings on the first square and multiply by  $2d$  for every subsequent square.

Ultimately the cousin count exceeds the population..... wait a minute... there's a flaw there somewhere. ☺

Most recently, I heard from a 5<sup>th</sup> cousin. Our common ancestors had a family of 11. So I must have a huge number of 5<sup>th</sup> cousins from that family and in the end the probability of hearing from one of them is not as low as I would have previously thought.

For genealogists the message is clear.... The further back you can get, the more likely you will hear from someone.... But everybody knows that anyway...☺

And even if you have few siblings and first cousins that you know about, there are potentially a huge number you have not yet found.

Generations Back	Cousin Degree	Number of Families	d=	Number of cousins of degree c		
				2	3	4
1	Parents	1	siblings	1	2	3
2	Grandparents	2		4	12	24
3	Great Grandparents	4		16	72	192
4	...	8		64	432	1536
5		16		256	2592	12288
6		32		1024	15552	98304
7		64		4096	93312	786432
8		128		16384	559872	6291456
9		256		65536	3359232	50331648
10		512		262144	20155392	402653184
